# Abstract

This thesis will discuss the work done towards improving the feedback provided to users of the Infandango system.

# Declaration

I declare that this thesis was composed by myself, that the work contained herein is my own except where explicitly stated otherwise in the text, and that this work has not been submitted for any other degree or professional qualification except as specified.

# Table of Contents

# Chapter 1

# Introduction

Infandango is an open source web-based system for automated grading of Java code submitted by students[7]. The aim of this project is to improve the feedback provided to students by using machine learning methods to display a visual representation of their current progress. In chapter 3 the design process will be discussed, explaining why certain choices were made. The implementation of these decisions will be discussed in chapter 4 with evaluation and conclusion following.

# Chapter 2

# Background

## 2.1 Infandango

Infandango is an automated web-based marking system for student submitted programming exercises. A student can view the list of warm-up, optional and core exercises and choose to submit a file for them. This file is then compiled and tested in a sandbox by Jester. Between the web frontend and Jester there is a PostgresSQL database which stores which files have been submitted for which users and how these files performed on the JUnit tests.

### 2.1.1 Current feedback

The current feedback provided is quite limited. Figure 2.1 shows some of the feedback a user currently receives. The user can also receive more in depth feedback about each submission, specifically the JUnit tests which are used to determine the mark. There is also a view which summarises the score for each week, allowing the user to judge their overall progress made.

## 2.2 Literature

Khan Academy[2] is a website which provides users with online education material:

> Our online materials cover subjects ranging from math and finance to history and art. With thousands of bite-sized videos, step-by-step problems and instant data

A blog post[6] written by David Hu about Khan Academy demonstrates that different feedback measures can affect user performance significantly. The original Khan

Academy system required a user to get 10 consecutive exercises of a certain type correct before they can be deemed proficient[1] at that type of exercise. In an attempt to improve this system, a logistic regression model is used to calculate the probability that a user passes the next exercise successfully, with a threshold of 94% representing the new proficieny level. Over a 6 day period 10% of users tested the new method. Users of the new system earned 20.8% more proficiences, attempted 15.7% more exercises and required 26% less exercises per proficiency. Hu summarises by saying the boost seems to come from allowing users to move on from exercises which they already proficient at, without requiring them to complete their streak thus wasting time on something they already understand.

[1] A proficiency is earned when a user is deemed to be ”proficient” at a certain kind of exercise

| | | | |
|---|---|---|---|
| 7 - [core] | Safer Fixed Divider | 4 / 5 | (80%) |
| 8 - [core] | Safer Quadratic Solver | 5 / 5 | (100%) |
| 9 - [core] | Squares Loop | 12 / 13 | (92%) |
| 10 - [optional] | Lopsided Number Triangle | 0 / 1 | ( 0%) |
| 11 - [optional] | Gambler's Ruin | 0 / 2 | ( 0%) |

# Chapter 3

# Design

With promising results for machine learning based visual feedback a similar design could be made for Infandango.

## 3.1 Language and Tools

Two languages are immediate possibilities for implementation: Java[3] and Python[4]. I had most experience with Java, and some parts of Infandango were already written in Java. Most of Infandango was, however, written Python and I had some experience with it as well. After researching appropriate languages for machine learning R[5] become a third possible choice. Follow research on all languages Python seemed most appropriate: integrating with Infandango would be straightforward and scikit-learn[1] would remove the challenge of implementing machine learning methods.

## 3.2 Proposed Design

Using anonymised data from previous years a model can be built using machine learning methods. Using this model and some recent scores from the user, the following score can be predicted. There is however an unsolved problem here: How is the model trained?

### 3.2.1 Model

The Khan Academy model is built based on one assumption: a user can always *generate another example* and it will be of the *same type*. These are two qualities which

Infandango does not share. Infandango has a preset number of manually written exercises and they are not grouped *strictly* by similarity. The first proposed model was to take the average for each week and use those averages as features for the model. Then we must ask what is the model predicting? The only reasonable thing for it to predict would be the subsequent week's score. Although the simplicity is appealing there are some problems with this model.

- If we are predicting the next week's score the problem turns into an estimating missing data problem, which is not a problem we want to solve
- Even after 3-5 weeks there would only just be enough data to start getting reasonable results CITE HERE
- Grouping data like this means we have a lot less training examples

A similar alternative to this model is to treat each question within a week separately, giving the model a much larger dimensionality. Although this does remove the latter two problems, the first problem still remains. This adds the extra problem which is how to deal with situations where a student doesn't attempt a certain question.
Both of these models have been working with the assumption that we want to learn something about *specific* questions. So if, for example, a question was particularly hard then the model might be able to learn that it should predict lower scores for that question. However, we have seen that using specific questions as features causes other problems. For this reason a much simpler model was created. The model has ***N*** features, each a percentage. Each feature represents a score from the corresponding previous question. The class is the score for the ***N+1*** problem, so when a user is using the system it will try to predict their next score given their previous ***N*** scores.

#### 3.2.1.1 Unexplored Alternatives

#### 3.2.1.2 Retrieving Data

#### 3.2.1.3 Machine Learning

Django is used to query the database and get test results for all users. These test results are filtered into groups of ***N+1*** consecutive results, with the final result being the class. For each set of ***K*** results ***K-N*** sets of results are created. This provides the machine learning methods with a lot more training data than alternative models.
Using sci-kit learn's cross validation method the data was then split into training and

testing sets, with a testing size of 20%. Different machine learning methods were then trained on this data and tested by comparing their R2 scores. In Figure 3.1 it can also be seen that these tests are done multiple times over different values of $N$. The highest accuracy is obtained by Logistic Regression at $N = 4$. Logistic Regression is also the most consitent of the methods, making it an appropriate choice.

## 3.3 Integration with Infandango
